Convert json format to array php. Convert json format to array php online. Php array to json format. How to print array in json format in php.

Since JSON is a ubiquitous data format for sharing and storing data, a PHP backend must allow JSON data processing. In this tutorial, we'll learn about the JSON format and convert PHP Object to JSON. Contents Definitions Array Array is a data structure that contains a group of elements. In case you want to go deeper in arrays, click here to get it done using the official documentation. Object Object is an individual instance of the data structure defined by a class. Example Object 1ObjectName: AnishaAge: 24Name: JosieAge: 29Examples of objects JSON JSON (JavaScript Object Notation) is one of the most popular open-standard file formats used for storing and sharing data json_encode() It is an inbuilt php function that is used to convert PHP array or object into JSON (JavaScript Object Notation) representation. json_decode() Takes a JSON (JavaScript Object Notation) encoded string and converts it into a PHP variable. Convert PHP Array to JSON First create an array. \$person = array('name' => 'Rhyley', 'email' => ''); To convert it we use json_encode(\$person). Print the array and the json. \$person = array('name' => 'Rhyley', 'email' => ''); print_r(\$person); echo "----- "; echo json_encode(\$person); Output Array ([name] => Rhyley [email] => ) ----- {"name": "Rhyley", "email": ""} Convert JSON To PHP Array For JSON (JavaScript Object Notation) to PHP Array we use json_decode. \$json = json_encode(\$person); // print the array print_r(json_decode(\$json)); Output ([name] => Rhyley [email] => ) Convert PHP Object to JSON Let's understand how we can JSON encode a PHP object by creating an instance of Fruits. Output: Array has 3 elements array values(\$arr) This function accepts a PHP array and returns a new array containing only its values (not its keys). Its counterpart is the array_keys() function. Use this function to retrieve all the values from an associative array. Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); print_r(array_values(\$data)); ?> Output: Array ([0] => Holmes [1] => Moriarty) array_keys(\$arr) This function accepts a PHP array and returns a new array containing only its keys (not its values). Its counterpart is the array_values() function. Use this function to retrieve all the keys from an associative array. Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); print_r(array_keys(\$data)); ?> Output: Array ([0] => hero [1] => villain) array_pop(\$arr) This function removes an element from the end of an array. Code: \$data = array("Donald", "Jim", "Tom"); array_pop(\$data); print_r(\$data); ?> Output: Array ([0] => Donald [1] => Jim) array_push(\$arr, \$val) This function adds an element to the end of an array. Code: \$data = array("Donald", "Jim", "Tom"); array_push(\$data, "Harry"); print_r(\$data); ?> Output: Array ([0] => Donald [1] => Jim [2] => Tom [3] => Harry) array_shift(\$arr) This function removes an element from the beginning of an array. Code: \$data = array("Donald", "Jim", "Tom"); array_shift(\$data); print_r(\$data); ?> Output: Array ([0] => Sarah [1] => Donald [2] => Jim [3] => Tom) each(\$arr) This function is most often used to iteratively traverse an array. Each time each() is called, it returns the current key-value pair and moves the array cursor forward one element. This makes it most suitable for use in a loop. Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); while (list(\$key, \$value) = each(\$data)) { echo "\$key: \$value "; } ?> Output: hero: Holmes villain: Moriarty sort(\$arr) This function sorts the elements of an array in ascending order. String values will be arranged in ascending alphabetical order. Note: Other sorting functions include asort(), arsort(), ksort(), krsort() and rsort(). Code: \$data = array("g", "l", "a", "s"); sort(\$data); print_r(\$data); ?> Output: Array ([0] => a [1] => g [2] => s [3] => l) array_flip(\$arr) The function exchanges the keys and values of a PHP associative array. Use this function if you have a tabular (rows and columns) structure in an array, and you want to interchange the rows and columns. Code: \$data = array("a" => "apple", "b" => "ball"); print_r(array_flip(\$data)); ?> Output: Array ([apple] => a [ball] => b) array_reverse(\$arr) The function reverses the order of elements in an array. Use this function to re-order a sorted list of values in reverse for easier processing—for example, when you're trying to begin with the minimum or maximum of a set of ordered values. Code: \$data = array(10, 20, 25, 60); print_r(array_reverse(\$data)); ?> Output: Array ([0] => 60 [1] => 25 [2] => 20 [3] => 10) array_merge(\$arr) This function merges two or more arrays to create a single composite array. Key collisions are resolved in favor of the latest entry. Use this function when you need to combine data from two or more arrays into a single structure—for example, records from two different SQL queries. Code: \$data1 = array("cat", "goat"); \$data2 = array("dog", "cow"); print_r(array_merge(\$data1, \$data2)); ?> Output: Array ([0] => cat [1] => goat [2] => dog [3] => cow) array_rand(\$arr) This function selects one or more random elements from an array. Use this function when you need to randomly select from a collection of discrete values—for example, picking a random color from a list. Code: \$data = array("white", "black", "red"); echo "Today's color is " . \$data[array_rand(\$data)]; ?> Output: Today's color is red array_search(\$search, \$arr) This function searches the values in an array for a match to the search term, and returns the corresponding key if found. If more than one match exists, the key of the first matching value is returned. Use this function to scan a set of index-value pairs for matches, and return the matching index. Code: \$data = array("blue" => "#0000cc", "black" => "#000000", "green" => "#00ff00"); echo "Found " . array_search("#0000cc", \$data); ?> Output: Found blue array_slice(\$arr, \$offset, \$length) This function is useful to extract a subset of the elements of an array, as another array. Extracting begins from array offset \$offset and continues until the array slice is \$length elements long. Use this function to break a larger array into smaller ones—for example, when segmenting an array by size ("chunking") or type of data. Code: \$data = array("vanilla", "strawberry", "mango", "peaches"); print_r(array_slice(\$data, 1, 2)); ?> Output: Array ([0] => strawberry [1] => mango) array_unique(\$data) This function strips an array of duplicate values. Use this function when you need to remove non-unique elements from an array—for example, when creating an array to hold values for a table's primary key. Code: \$data = array(1, 1, 4, 6, 7, 4); print_r(array_unique(\$data)); ?> Output: Array ([0] => 1 [3] => 6 [4] => 7 [5] => 4) array_walk(\$arr, \$func) This function "walks" through an array, applying a user-defined function to every element. It returns the changed array. Use this function if you need to perform custom processing on every element of an array—for example, reducing a number series by 10%. Code: function reduceBy10(&\$val, \$key) { \$val -= \$val * 0.1; } \$data = array(10, 20, 30, 40); array_walk(\$data, 'reduceBy10'); print_r(\$data); ?> Output: Array ([0] => 9 [1] => 18 [2] => 27 [3] => 36) Published: July 18, 2005, 8:53 AM PDT Modified: June 8, 2007, 9:58 AM PDT See more Developer
